

***Mapping seabed sediments
with
single- and multifrequency
multibeam backscatter data***

Ph.D. candidate Timo C. Gaida

Group Acoustics, Faculty of Aerospace Engineering, Delft University of Technology

1) Introduction

- Acoustic Backscatter
- Sediment Classification

2) Single-frequency backscatter classification

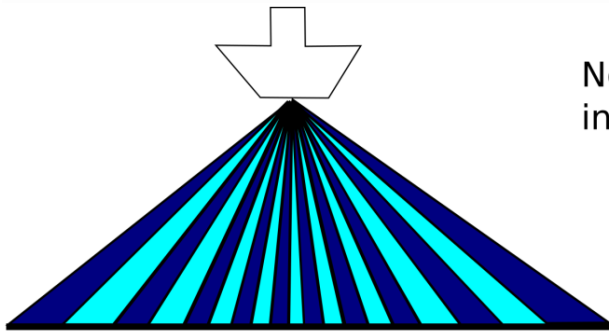

- Cleaverbank (Dutch North Sea)

3) Multi-frequency backscatter classification

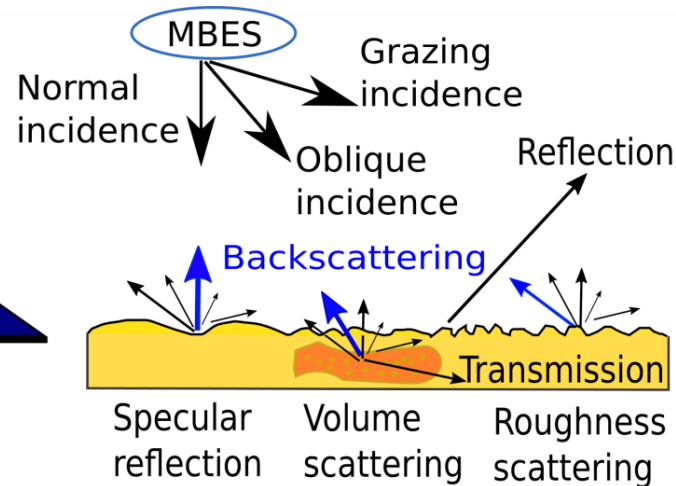

- Bedford Basin (Canada)

Multibeam echosounder (30 – 700 kHz)

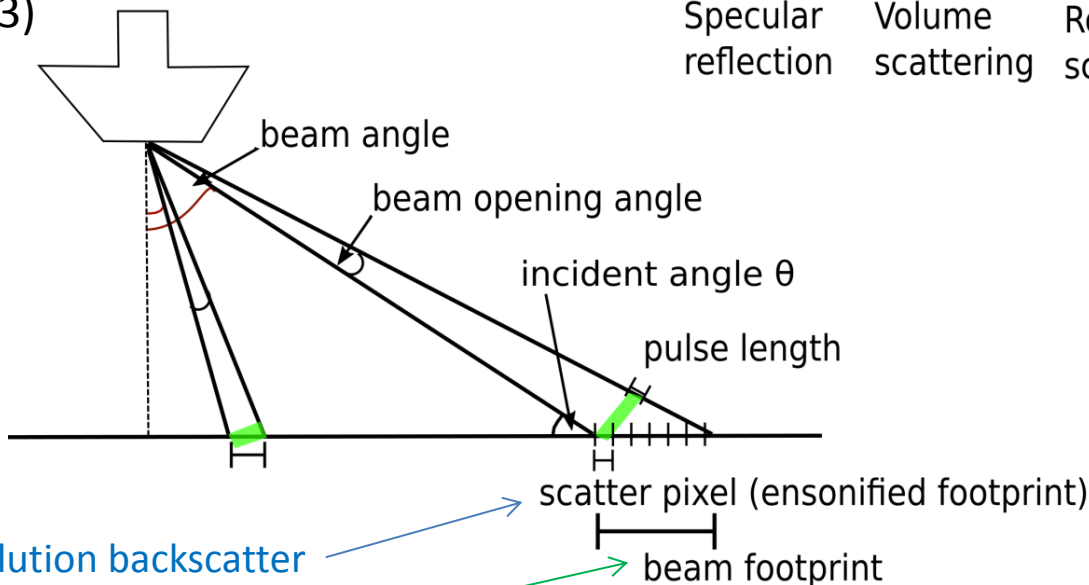

1)

2)

3)

Backscatter strength is dependent on

- seabed properties
- incident angle
- frequency

Resolution backscatter

Resolution bathymetry

Classification

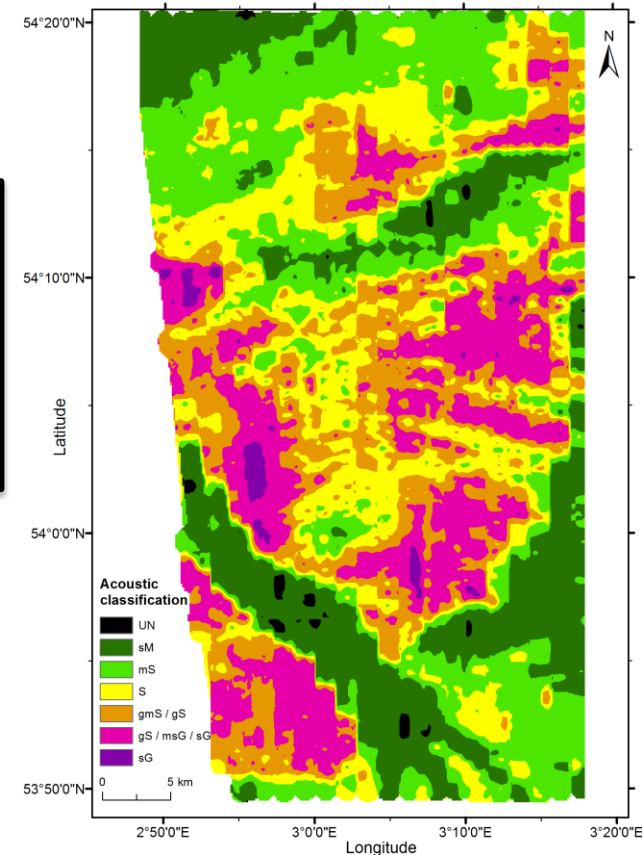

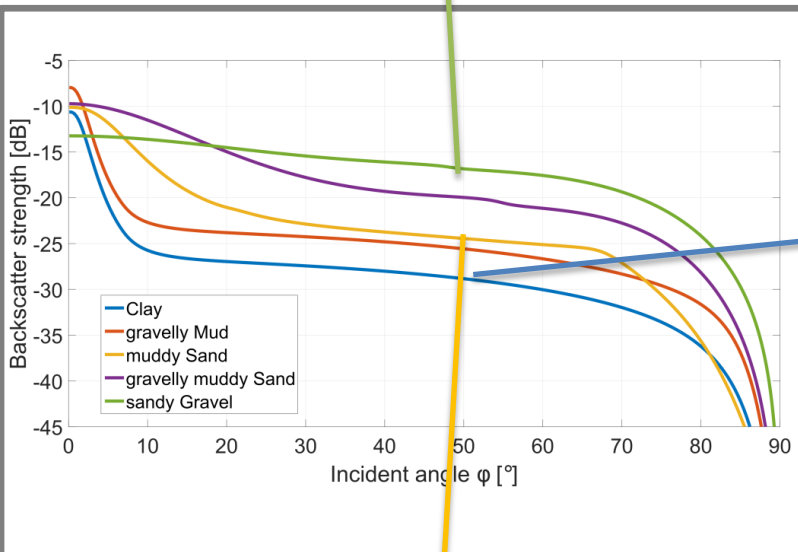

Uses *features* or *parameters* to characterize an object

Features: backscatter, bathymetry, slope etc.

Object: sediment types, benthic habitats

Method: *unsupervised* (e.g. TU Delft methods)

supervised (e.g. machine learning)

Unsupervised seabed classification

BS is dependent on seabed properties, incident angle and frequency

Reference: [2]

Theory

Requirement:

Sufficient number of measurements
→ follows Gaussian distribution

Result:

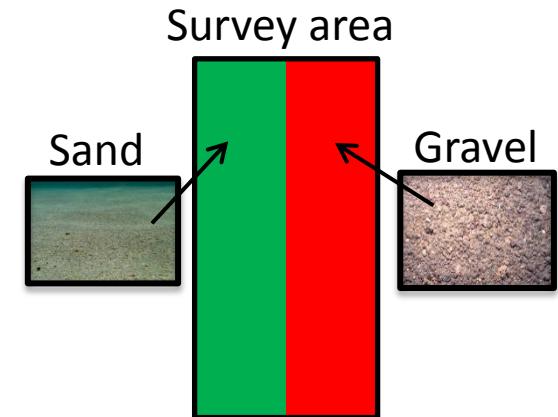

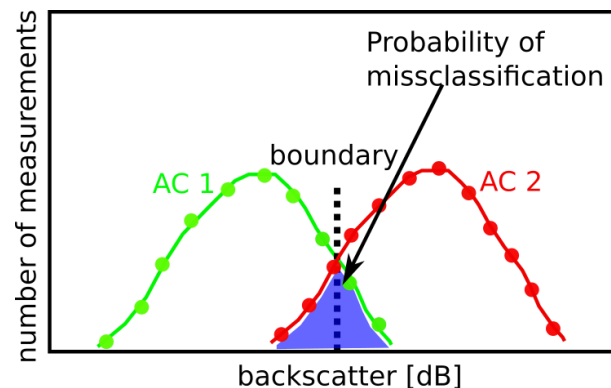

Gaussian = specific substrate

Statistical estimates:

-BS boundaries between sediment types
→ Acoustic class (AC)
-probability of missclassification

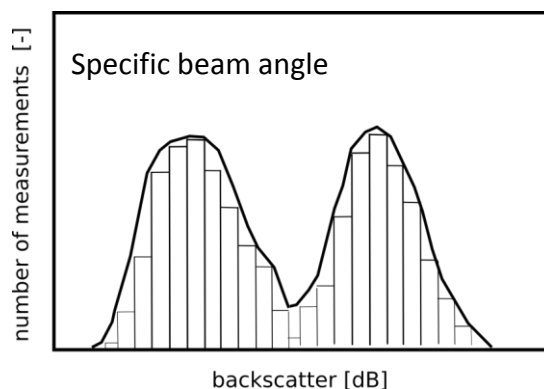

Applied to:

- Backscatter from a single frequency
 - Backscatter from a single beam angle
- >>> sediments along the swath can be resolved

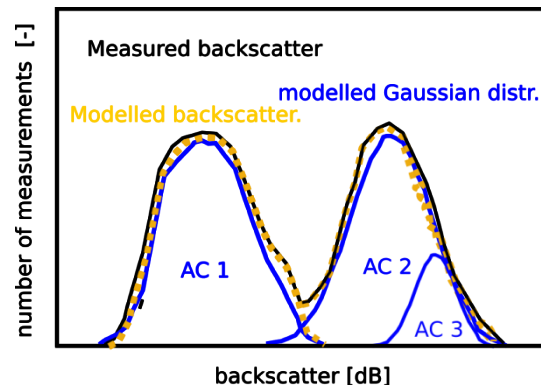

Example

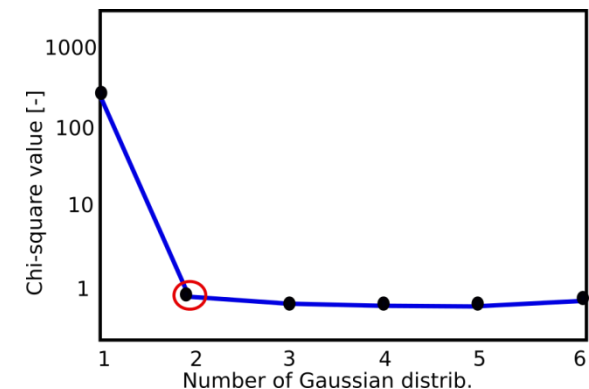

Measured backscatter histogram

Fit of Gaussian distribution

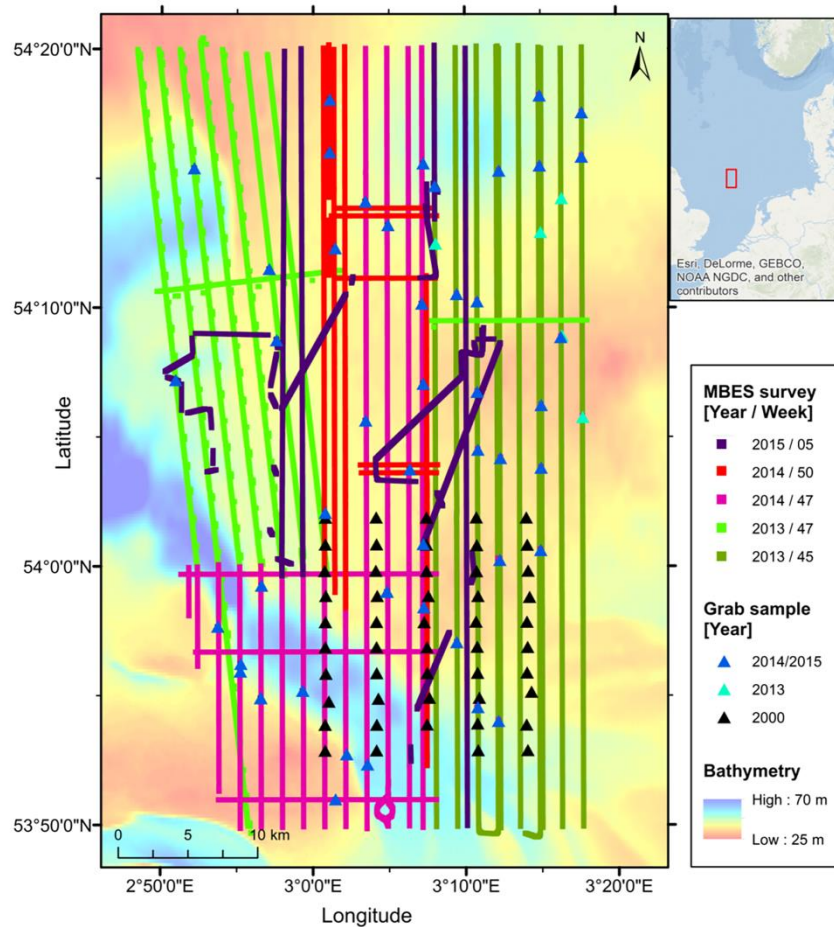

Chi-square test

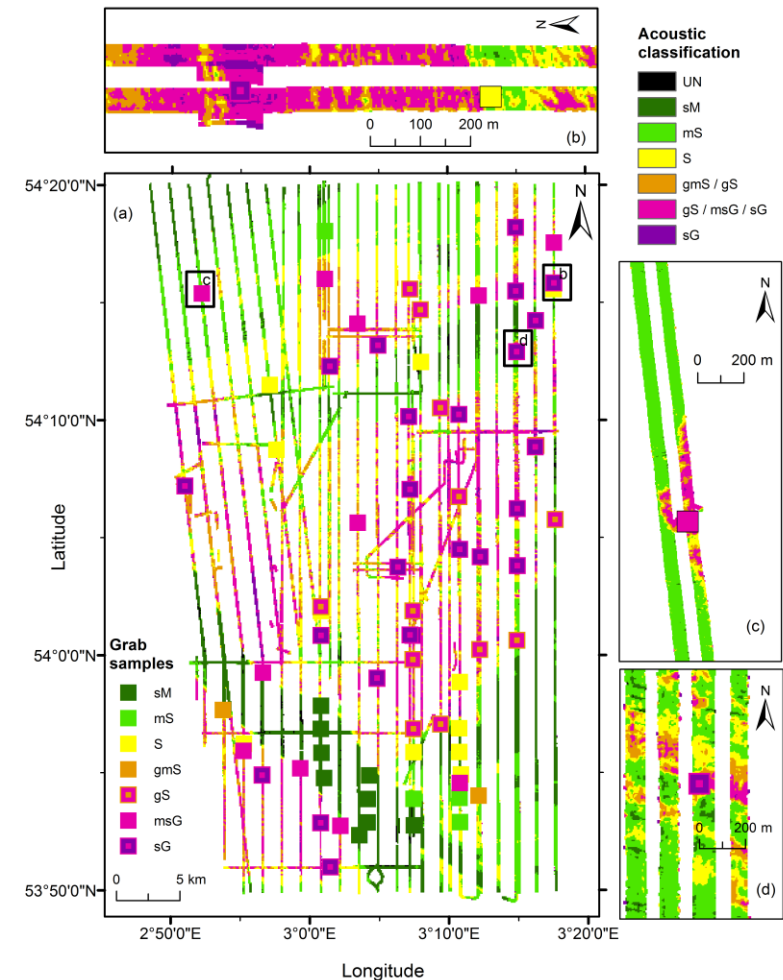

Cleaver Bank –Survey area

- Kongsberg EM 3002 – 300 kHz

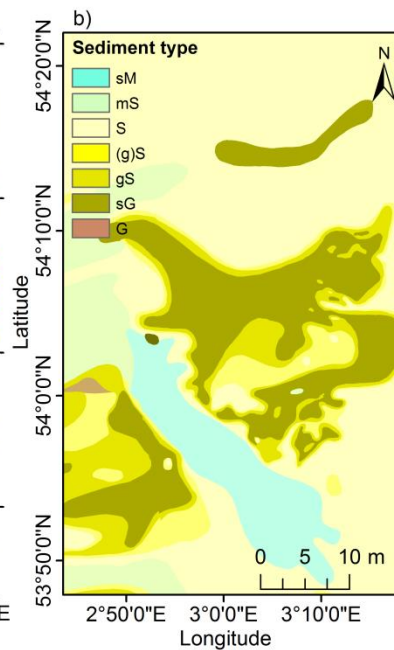

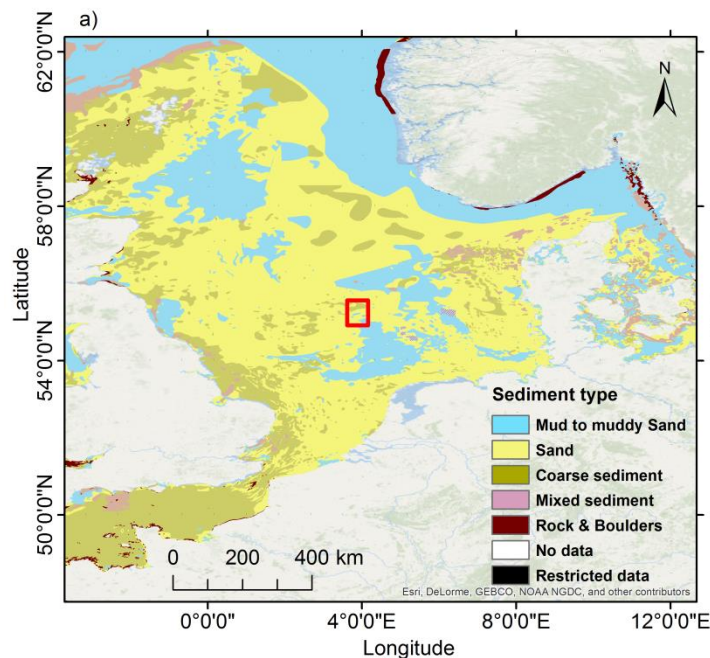

Seabed substrate maps

- Multibeam backscatter
- Ground truth samples
 - Acoustic seabed classification

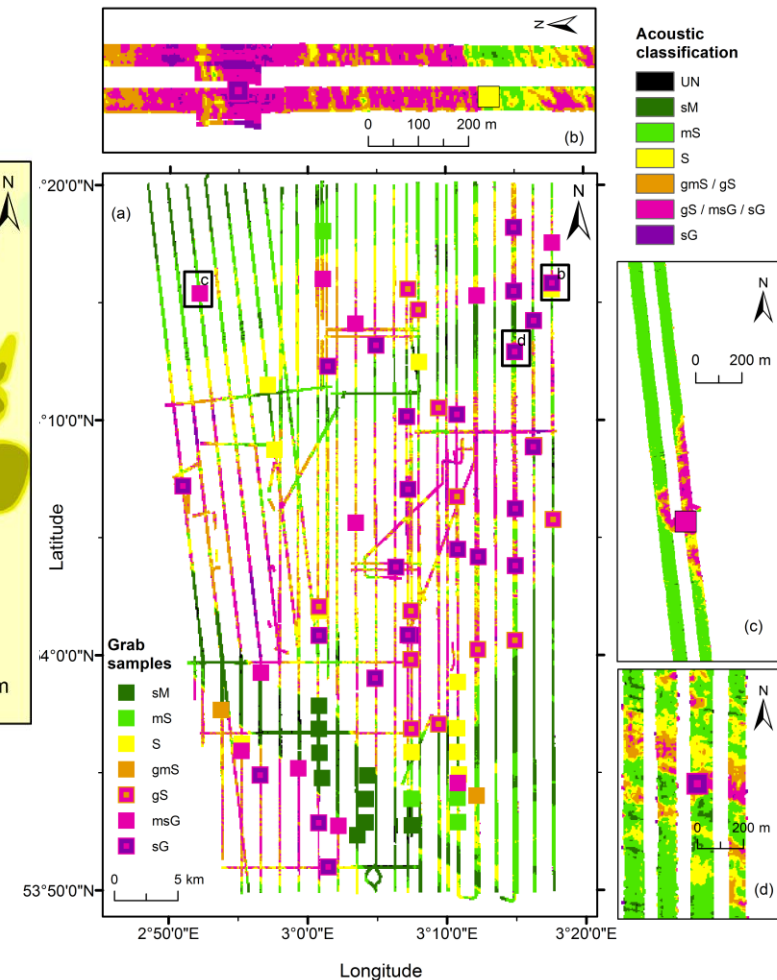

Seabed substrate maps (EMODnet portal)

- Samples
- Bathymetry
- Seismic
 - Manual interpretation

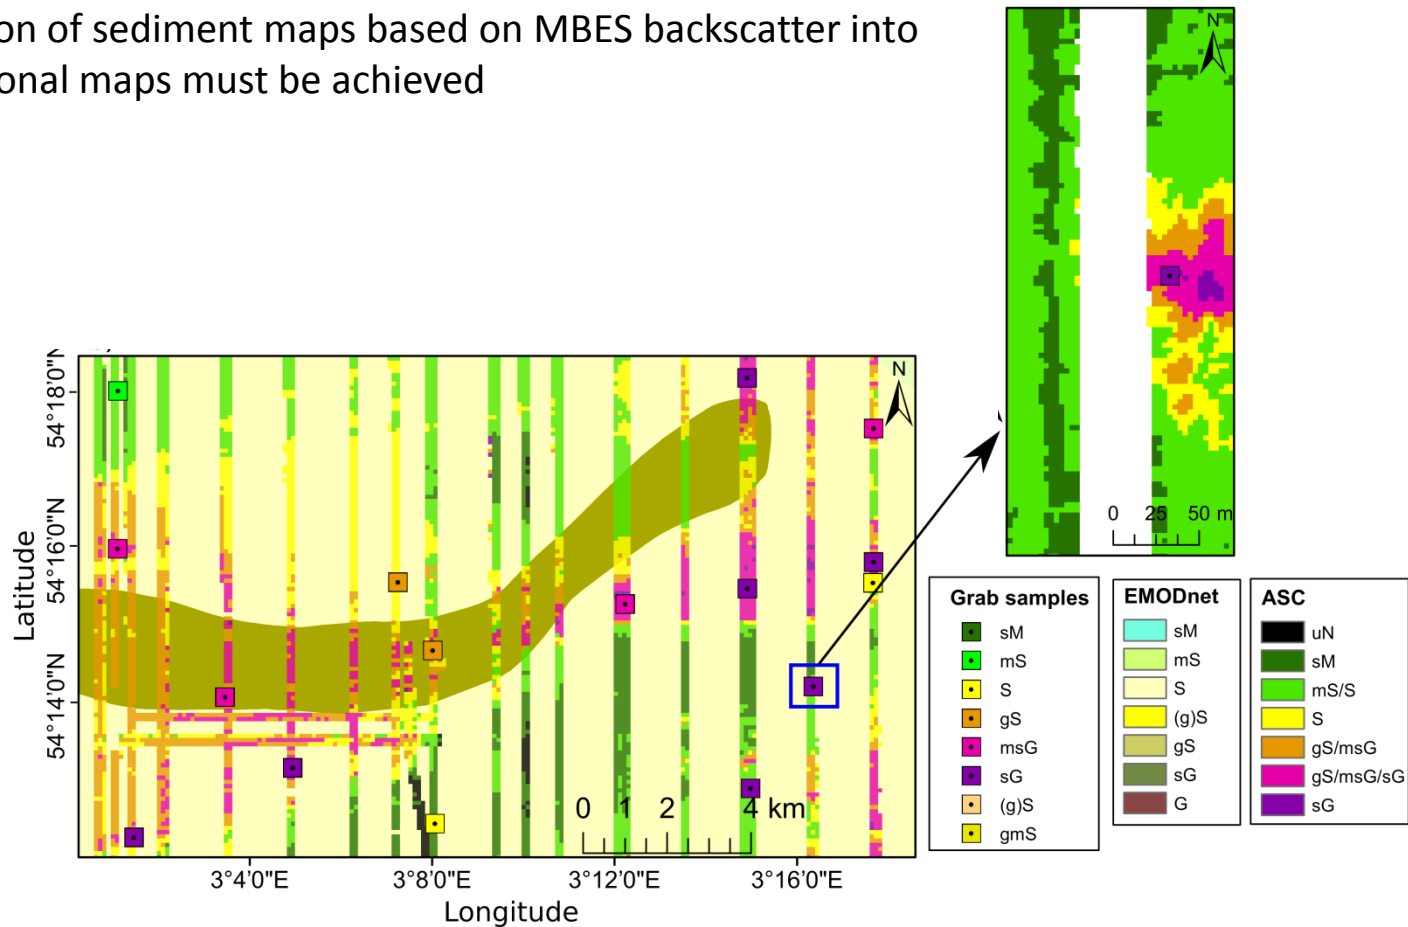

Seabed substrate maps

- Multibeam backscatter
- Ground truth samples
 - Acoustic seabed classification

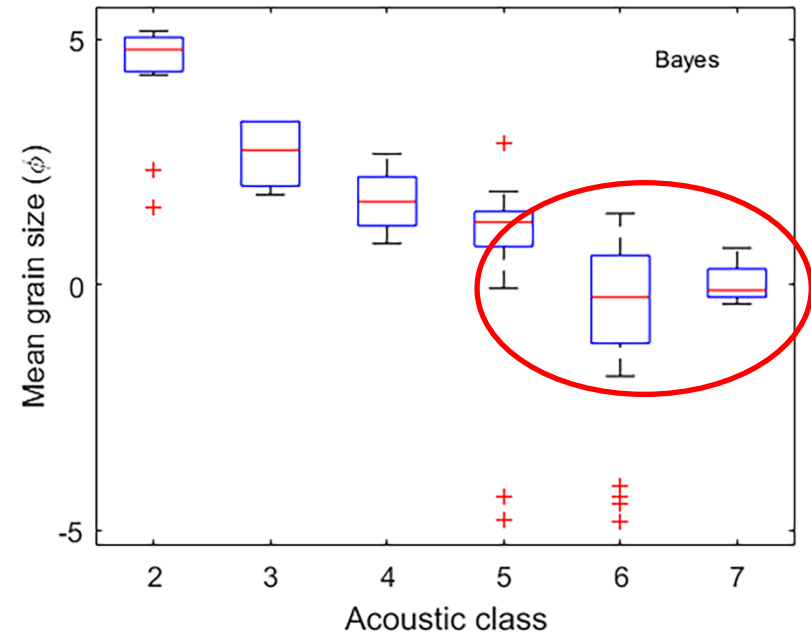

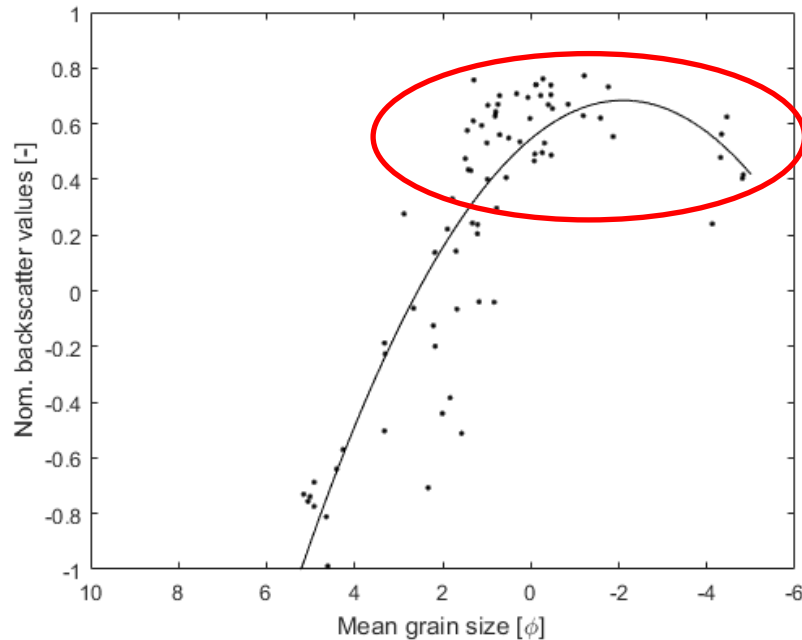

Sediment classification based on MBES backscatter yields to much finer spatial discrimination of sediments

- Enables sediment maps with high spatial coverage and resolution
- Integration of sediment maps based on MBES backscatter into conventional maps must be achieved

Correlation between Acoustics and Ground Truth

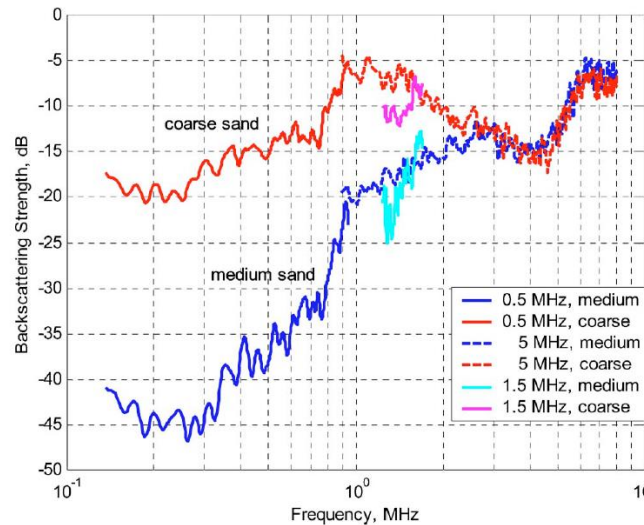

- Ambiguity observed for coarse sediments (\sim gravelly sand to sandy gravel)

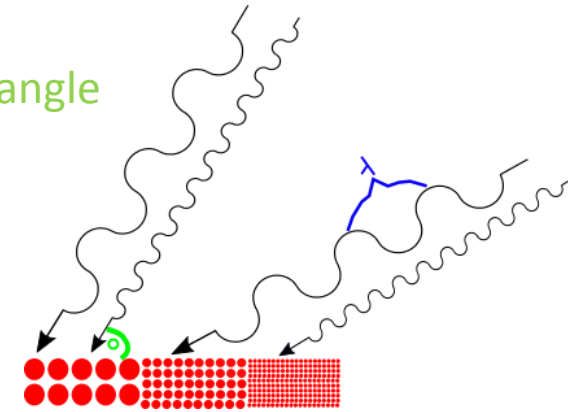

Multifrequency backscatter might be a solution to solve this ambiguity

Increasing the acoustic discrimination by using multi-frequency backscatter

Acoustic backscatter is dependent on seabed properties, incident angle and frequency

Reference: [4]

Frequency dependency of acoustic backscatter

Acoustic wavelength influences:

(1)

Relationship to
(seabed) roughness

(2)

Signal penetration depth
(Volume scattering)

(3)

Scattering regime
(Rayleigh to geometric
scattering)

What are the challenges?

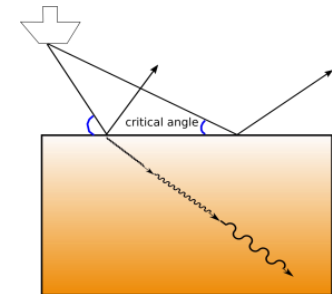

1) Appropriate data processing for multi-frequency data

2) Classification method to combine information from different frequencies in a single map

3) What part of the seabed is represented per frequency

R2 Sonic 2026

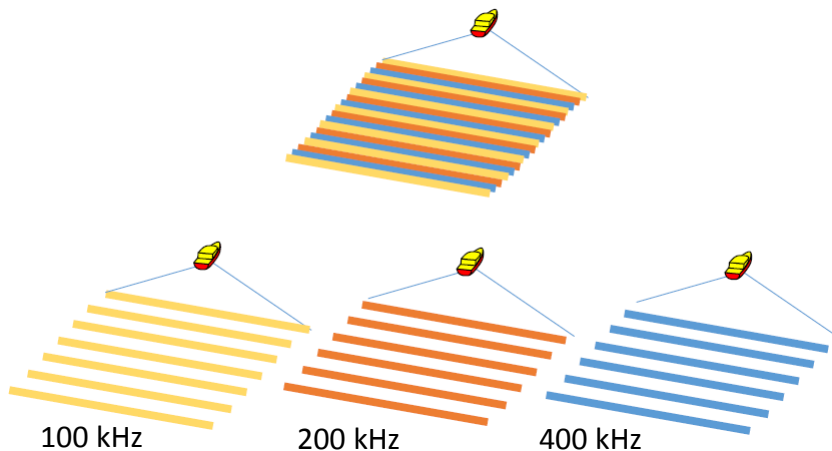

Broadband multibeam system

- 90 kHz
- 200-450 kHz, 1 Hz granularity
- Up to 5 frequencies on a ping-by-ping basis

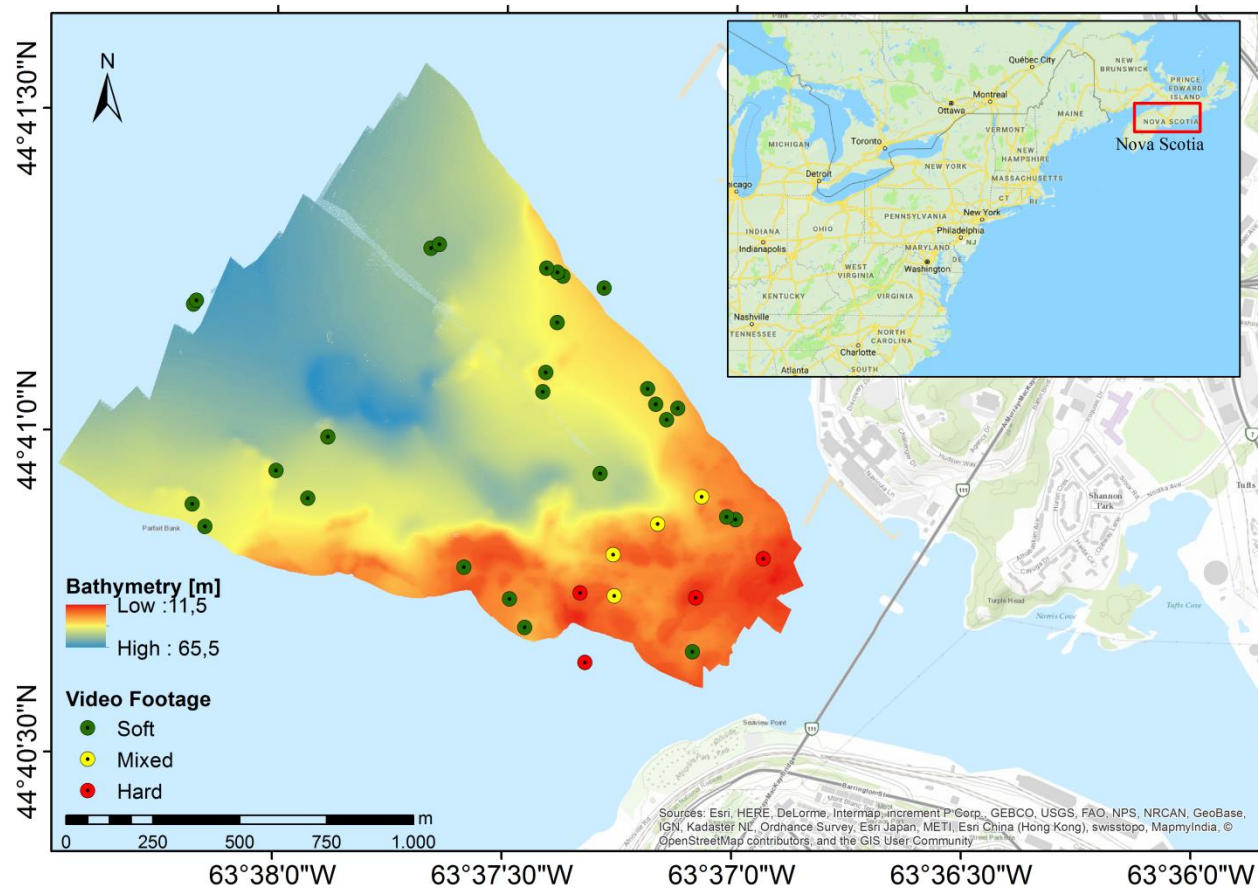

Single mapping campaign, Single vessel, single sensor provides sampling over widely spaced frequencies

Multispectral mode

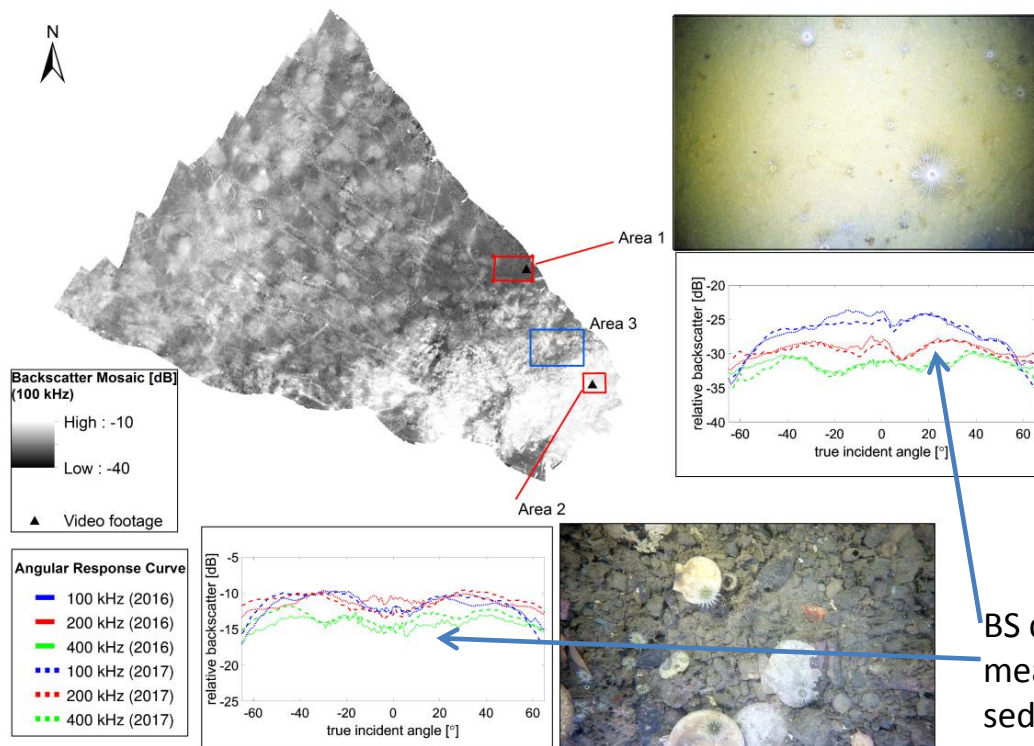

- 2 surveys in 2016 and 2017
- 100, 200 and 400 kHz
- Video footage

Bathymetry map 2016

Influence of frequency on:

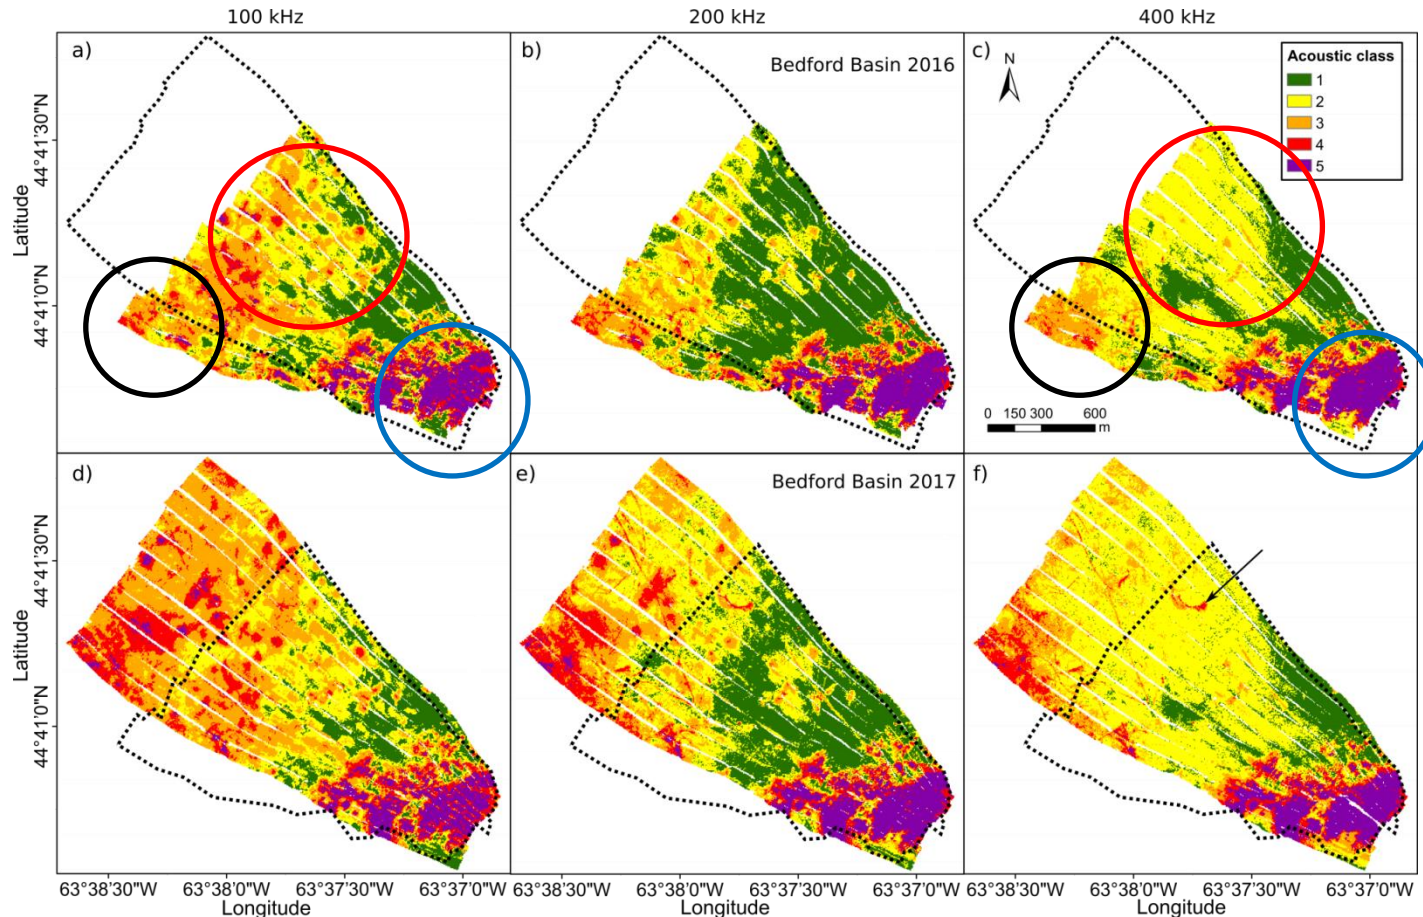

- Receiver sensitivity
- Ensonification area of signal
- Absorption
- Directivity pattern at transmission
- Directivity pattern at receptions
- Gains

Verification of data processing

- 2 homogeneous areas (soft and hard sediment)
- Consistent ARC's between MBES backscatter measurements in 2016 and 2017
 >>> indicates correct processing

Single-frequency classification maps

Reference: [5]

Observations

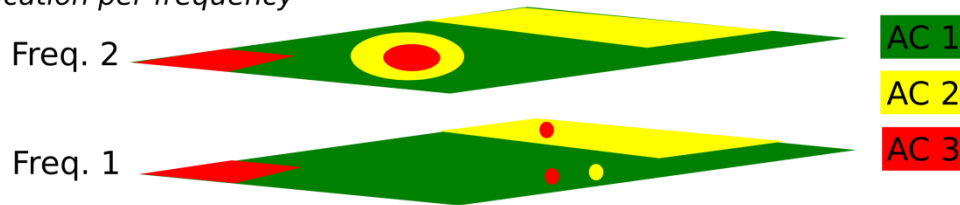

- Different spatial acoustic patterns at each frequency
- Observed frequency dependency of BS
 - ✚ Fine sediment (~mud)
 - ▬ Coarse sediment (gravel, shell, reef)

How to combine these information into a single map?

Multispectral Bayesian Classification - Workflow

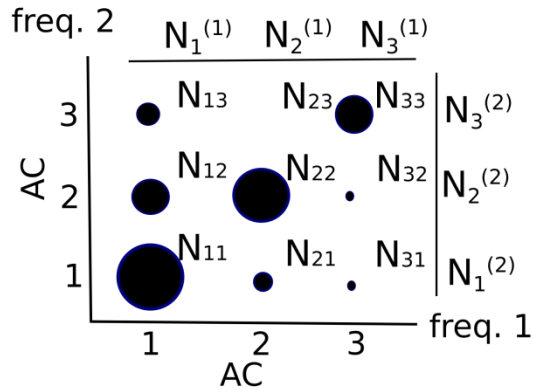

Step 1

Classification per frequency

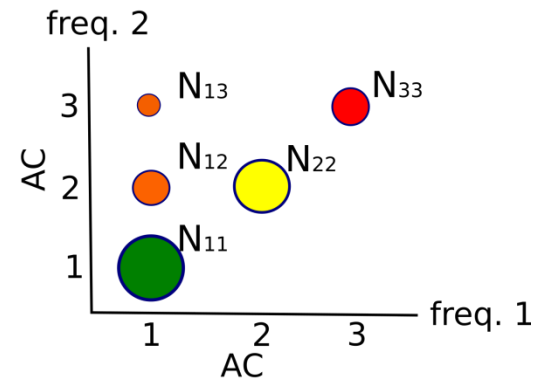

Step 2

Error matrix

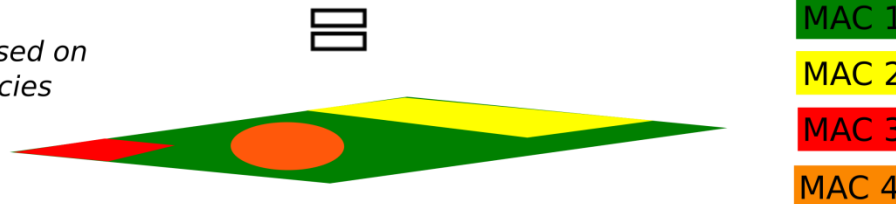

Step 3

Statistical significance test

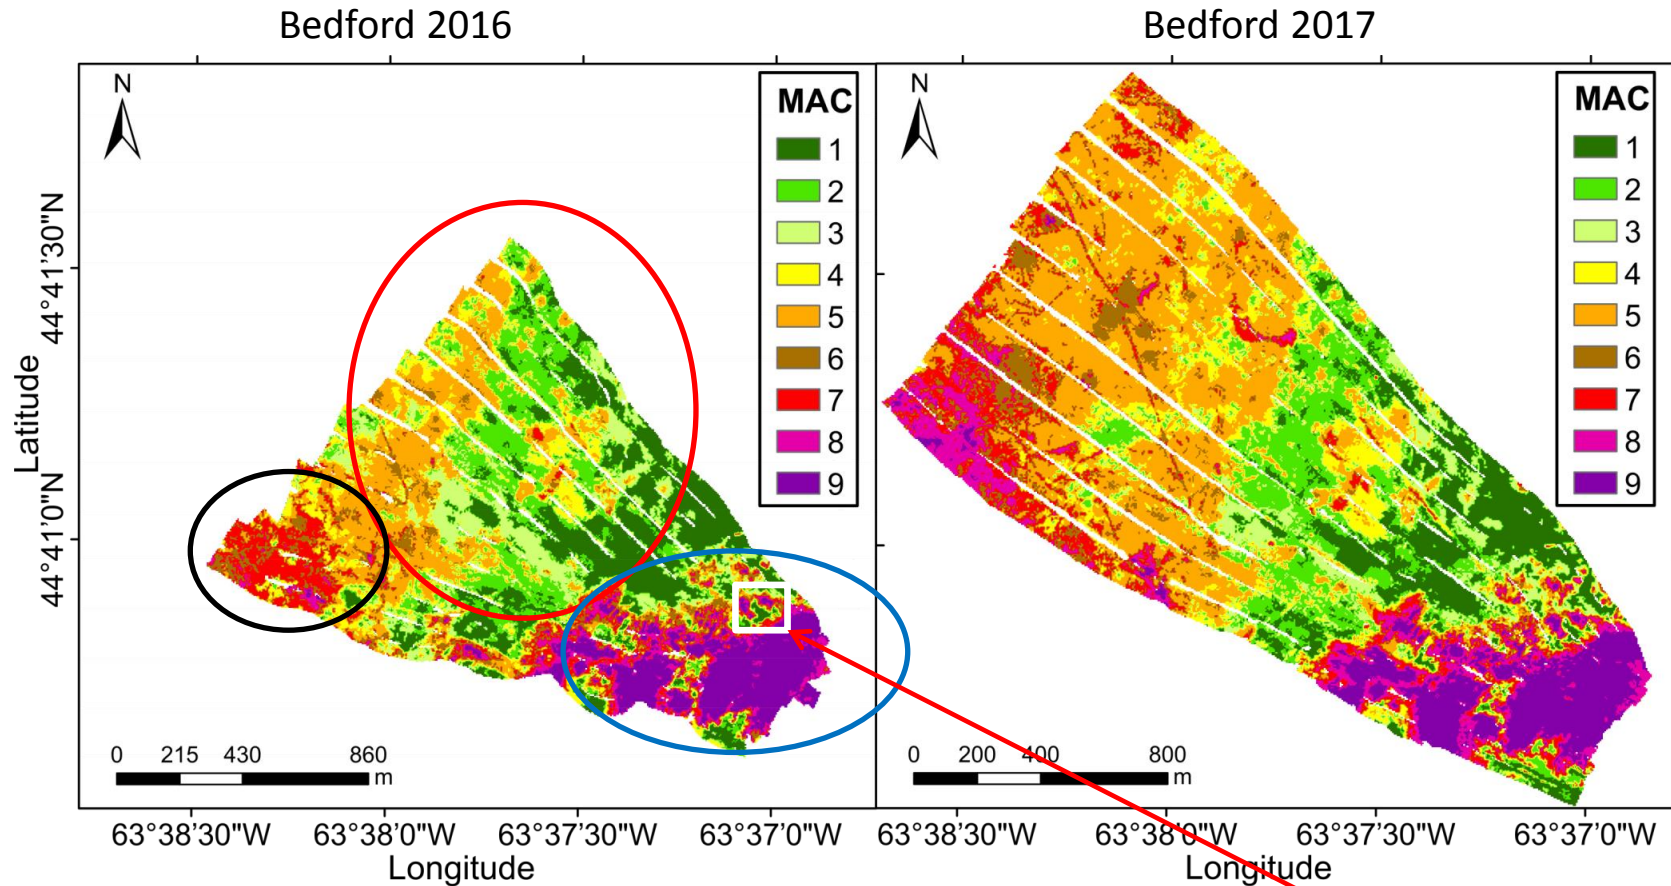

Step 4

Classification based on multiple frequencies

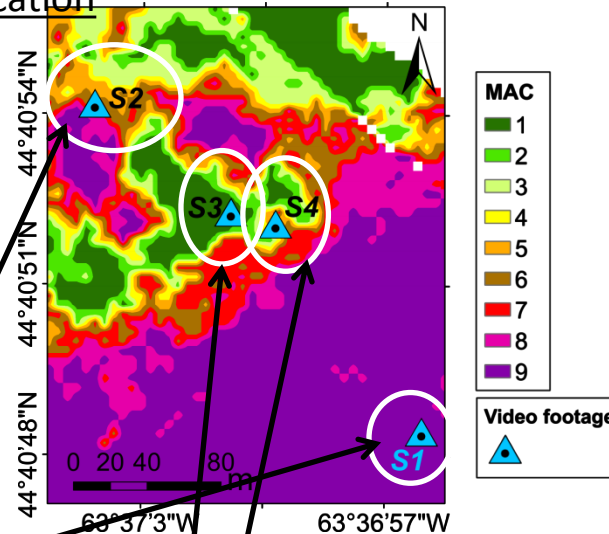

Multi-frequency classification maps

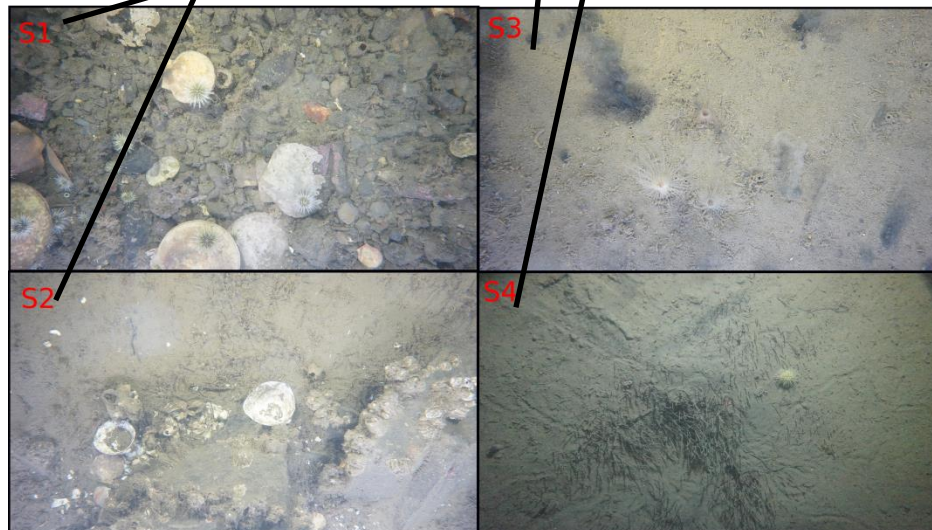

- Acoustic information per single frequency are combined in a single map
- Robust and repeatable classification method for multispectral backscatter data
- Most benefit is visible for fine sediments (for this specific survey area)

Qualitative comparison with video footage

Multispectral acoustic classification

Video footage

S1 extensively hard sediment (gravel, boulders, shell, coral)

S2 mix hard (gravel, boulders, shell, coral) and soft sediment (mud, fine sand)

S3 soft sediment (mud, fine sand) with flora and gas seeps

S4 soft sediment (mud, fine sand) with flora and fauna
